1.0 Introduction

A team comprised of the Massachusetts Water Resources Authority (MWRA), Fay, Spofford & Thorndike (FST) and the University of Massachusetts at Amherst (UMass Amherst), hereinafter referred to as the “Team”, undertook a laboratory bench-scale study to evaluate the anaerobic co-digestion of food waste (FW) and sewage sludge (SS) from the Deer Island Treatment Plant (DITP). The study’s objectives were to determine the following for several FW/SS mixtures:

- Anaerobic digestibility.
- Biogas (methane) production.
- Volatile solids reduction.
- Side-stream impacts for nutrient load.

MWRA is conducting another study to evaluate the feasibility of the sludge digestion and downstream sludge handling processes to accommodate FW in terms of capacity, process changes, access issues, etc., and the results of both of these studies will be necessary to determine the future of FW co-digestion at DITP.

Background Information

FW and other organics represent 20-25% of the current waste stream in Massachusetts going to incinerators or landfills. The Massachusetts 2010-2020 Solid Waste Master Plan calls for the diversion of at least 35% of FW from disposal by 2020. Anaerobic co-digestion of FW and SS is a sustainable approach that combines wastewater treatment with the recovery of useful byproducts and renewable biofuels. Adoption of anaerobic co-digestion could reduce reliance on fossil fuels, limit air pollutant emissions, provide supplemental energy and reduce landfill and incineration waste.

The anaerobic digestion process at DITP is comprised of three digester modules, each containing four egg-shaped anaerobic digesters. Each digester tank is 90 feet in diameter at the middle with a liquid level depth of 128 feet, and each has a capacity of 3.0 million gallons. The system is used for the digestion of thickened primary and waste activated sludge. Each digester module is arranged in a rectangular pattern with an equipment building located in the center of each module. The equipment buildings house sludge and gas piping, along with sludge heat exchangers, sludge recirculation pumps and other related process equipment. There are also two sludge/gas storage tanks located adjacent to digester module 1. The capacity of each sludge/gas storage tank is also 3.0 million gallons. At present 8 of the 12 digester units are operated, so there appears to be significant capacity available for the addition of FW. Because of the large size of these digesters, DITP could play an important role in helping to meet the goals of the Solid Waste Master Plan while reducing the facility’s dependence on fossil fuel, increasing its production of biogas - a renewable energy source, and becoming more energy-efficient.

Literature Review

Co-digestion of FW with SS in anaerobic digesters at existing wastewater treatment plants is a relatively new idea in the U.S. There are several WWTPs that are currently co-digesting FW and SS, all of which have started this practice fairly recently. It is becoming more prevalent now that the potential of utilizing the additional biogas produced as a renewable energy source is realized, and more strict regulations concerning the disposal options for organic wastes are being implemented.

Co-digesting of FW and SS provides many benefits. It increases the digestibility of the sludge, increases biogas production of anaerobic digesters and provides an alternative disposal method for the generators of FW. Because the volatile solids (VS) conversion rate of the combined waste is much higher than that of SS alone (up to 90% for combined FW and SS compared to approximately 50% for SS alone), the amount of biogas produced as a byproduct of digestion is much higher.

The amount of VS destroyed during co-digestion can vary greatly (approximately 7% to 90%) based on the type of FW that is being co-digested, the FW characteristics, the loading ratio of FW to SS and the amount of FW being added. Different types of organic waste that can be co-digested include fats, oils and grease (FOG), high-strength wastes (HSW) and source-separated organics (SSO). FOG consists mainly of frying oils and grease from grease traps, HSW are typically wastes from food processing/production facilities, and SSO are materials that are separated from solid waste from various sources such as restaurants, supermarkets and food and beverage manufacturers (Wimmer et al., 2012).

Even though FW is more digestible than SS, it requires the micronutrients found in the wastewater sludge to complete the digestion process. It has been found that when FW is digested on its own, without sludge, the volatile solids reduction (VSR) and biogas production rates are much lower than with co-digestion. Co-digesting, or combining the different types of wastes, results in a synergistic outcome (Zitomer et al., 2008). This is due to changes in the digester microbial community structure during co-digestion that lead to more rapid, extensive conversion of the biodegradable substrate to biogas. The co-digestion of the mixed wastes supports different bacterial and methanogenic degradation pathways, which leads to a more rapid methane production rate through enhanced microbial activity (Navaratnam et al., 2012). Because of the more rapid conversion of the combined waste to biogas, a shorter solids retention time (SRT) in the digesters is required. When FW or SS are digested on their own, the degradation pathways are limited, which slows the conversion process.

Navaratnam et al. (2012) completed a full-scale co-digestion study and measured the biochemical methane potential (BMP) of primary sludge combined with different food and manufacturing wastes. It was found that the measured BMP for the sludge mixed with FW was higher than the theoretical BMP for the combined wastes. Other results of this study include an increase in specific methanogenic activity due to the increase in different species in the digesters as opposed to an increase in the total number of all methanogens present.

Wang et al. (2012) is currently conducting a study comparing the effects of co-digestion with different ratios of grease trap waste to SS. This study is being conducted in phases (using 0% to 100% grease trap waste) to determine the optimal amount of grease trap waste required to maximize the biogas production as well as the maximum fraction of grease trap waste that can be co-digested without methanogenic inhibition. Because the results of this study have not yet been published, no comparison can be made with MWRA's study regarding the biogas production and VSR of 100% grease trap waste.

The addition of FW to SS not only increases VSR and biogas production, it also stabilizes the digester performance and improves the carbon content of the digested sludge due to the higher C:N ratio. Co-digestion also affects the amount of solids produced as an end product. The FW is not completely converted to biogas, therefore the solids produced will range from approximately 10% to 30% of the volatile portion of the FW entering the digesters, depending on the amount of VSR occurring. Co-digestion may also affect the liquid treatment train due to higher levels of ammonia and COD in the filtrate of the dewatering activities. These increased levels of contaminants may require additional treatment as the current nitrogen output is nearing the maximum permitted capacity.

Also, to accommodate the additional FW loading to the digesters, more heat to the digesters will be required to maintain the optimal conditions for anaerobic digestion of the mixed sludge. However, with an efficient combined heat and power recovery system installed, the heat required for digestion can be obtained from the additional biogas produced from the FW addition.

2.0 Approach

The Team used a three-phase approach to evaluate the co-digestion of SS and FW at DITP:

- Phase I: Characterize FW samples provided by Waste Management, Inc., and four SS samples from DITP – primary, secondary, digester feed (combined primary and secondary) and digested sludge.
- Phase II: Conduct a bench-scale study for FW and SS using a batch digestion process.
- Phase III: Conduct a bench-scale study for FW and SS using a semi-continuous digestion process.

For Phases II and III, the study evaluated the following criteria for various FW/SS combinations:

- Anaerobic digestibility.
- Biogas production.
- Volatile solids reduction.
- Side-stream impacts for nutrient load.

All three phases occurred at the UMass Amherst Environmental Engineering Laboratory under the direction of Professor Chul Park, Ph.D., in collaboration with MWRA and FST.

3.0 Food Waste and Sewage Sludge Characterization

The Waste Characterization was conducted in November 2012 on three days: November 8, 14 and 28, 2012. The wastes analyzed were as follows:

- November 8, 2012 – FW, primary, secondary and digested sludge
- November 14, 2012 – FW (second set)
- November 28, 2012 – FW, combined primary and secondary sludge and digested sludge

Waste Management, Inc., a waste transportation and management company, provided the FW, which was an “engineered” blend of foods that the company replicated several times during the bench-scale study. The blend of foods resulted in a slurry with a total solids (TS) concentration of about 15%. DITP supplied the primary, secondary, combined primary and secondary (feed) sludge and the digested (seed) sludge. Samples analyzed on November 28, 2012 represent those used for the batch digestion process. All sludges were shipped or transported in coolers with ice and refrigerated until analyzed.

Table 1 shows the parameters and specific analytical method/instrumentation used, and Tables 2 - 4 present the analytical results for the FW and SS samples taken on the various dates in November 2012.

Table 1
Characterization Study Parameters and Analytical Methods

Parameters	Methods / Instruments	Standard Methods
pH	pH Meter (Orion GS9156)	4500-H+B
STN	Hach reagent sets	-
SPO ₄	Hach reagent sets	-
COD	Standard Methods	5220D
TS and VS	Standard Methods	2540
Alkalinity	Standard Methods	2320
Capillary Suction Time (CST)	Standard Methods	2710G

Table 2 and Table 4 both indicate that the FW samples from November 8 and November 28, 2012 have much lower alkalinity and pH values, higher TS and VS concentrations, and higher VS/TS percentage than the primary, secondary, digested and feed sludges. Table 3 presents the soluble chemical oxygen demand (SCOD) for a FW sample taken on November 14, 2012, since this analysis was not done on November 8, 2012. The SCOD result is much higher than those of the sludges analyzed on November 8th and November 28th, and TS and VS values for the FW on November 14th are similar to those for FW analyzed on November 8th and November 28th.

4.0 Phase II – Bench-Scale Batch Digestion Study

General

The batch digestion study began November 28, 2012 with a one-time slug feeding of various combinations of FW and SS to seed sludge (digested sludge) from DITP in eight 4-liter reactors. The batch digestion setup did not represent digestion operation at DITP with respect to digester feed (pounds of VS feed per pounds of VS in the digester), sludge withdrawal and/or the anticipated ratio of FW feed to the mass of VS in the digester. The purpose of this preliminary batch study was to evaluate the co-digestibility of FW under extreme conditions with respect to FW/SS feed, seed sludge, environmental factors, etc. The study was also done to determine how various FW/SS ratios affect biogas production, VSR, pH, alkalinity and other parameters that were useful to know in preparation for the semi-continuous digestion study.

Batch Study Setup

The eight 4-liter reactors were kept in a temperature-controlled room with the temperature set at 37°C to simulate the mesophilic conditions of the anaerobic digesters at DITP. Each digester was closed with a rubber stopper through which two glass tubing sampling ports were pierced. The first piece of glass tubing was used as a sampling port for biogas, through which the biogas was collected into a plastic gas bag. The second sampling port was used to withdraw digested sludge for measurement. Each digester was seeded with 2 liters of field-combined primary and secondary anaerobically digested sewage sludge collected from DITP. The contents were stirred at 100 rpm using constructed rotating chambers. Figure 1 displays the reactor setup.

Figure 1
4-Liter Reactors for Batch Digestion Study

Table 5 presents the breakdown in feed composition for the eight reactors/digesters. As the table indicates, FW percentages in the feed to the digesters varied from 0% (all DITP feed sludge and no FW), to 88.5% (FW and seed sludge from DITP digesters, and no DITP feed sludge). Intermediate FW percentages were 6.1%, 11.7% and 21.6%, with two reactors dedicated to each of these percentages, and one reactor each for the 0% and 88.5% FW. The percentages were on a dry weight basis and represent FW as a percent of total digester contents.

Table 5
Batch Digestion Setup

FW/Total Reactor Sludge %	Food Waste (L)	Feed Sludge (L)	Seed Sludge (L)	Number of Reactors
88.5% food waste	2	0	2	1
100% feed sludge/0% food waste	0	2	2	1
6.1% food waste	0.05	1.95	2	2
11.7% food waste	0.10	1.90	2	2
21.6% food waste	0.20	1.80	2	2
Total number of digestion setups				8

Sampling of the digester supernatant occurred several times throughout the study (Table 6). Sampling for biogas collected in bags attached to the digesters took place daily in the first 5 days, and then at a reduced rate as biogas production decreased. Sampling parameters and analytical methods/instrumentation used are shown in Table 7.

Table 6
Batch Digestion Supernatant Sampling Schedule

Days of Digestion	Sample Date

CST	Standard Methods	2710G

Bench-Scale Batch Study Results and Discussion

Figures 2 and 3 display alkalinity and pH sampling results, respectively, for the various FW/SS combinations.

Figure 2
Batch Digestion Alkalinity

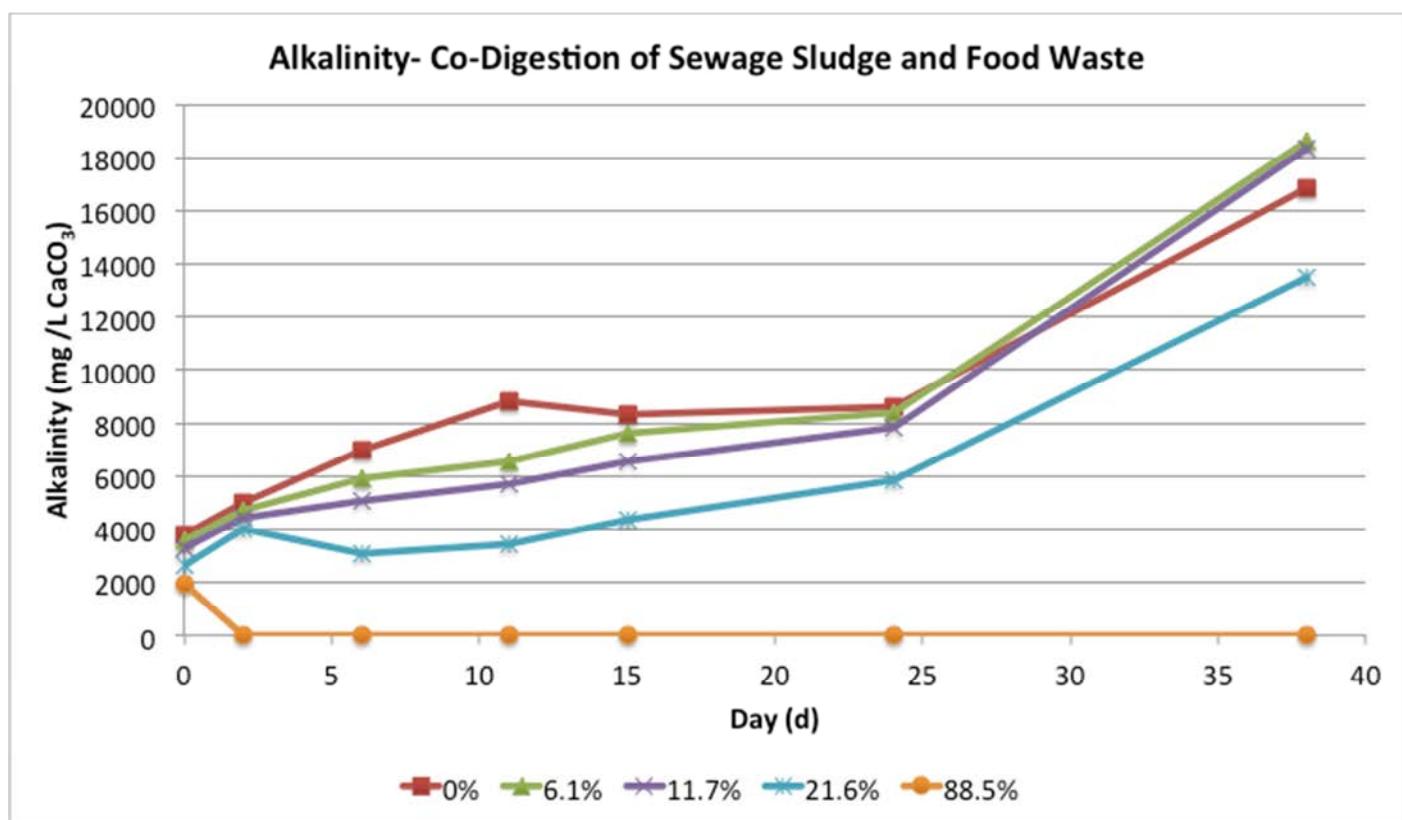

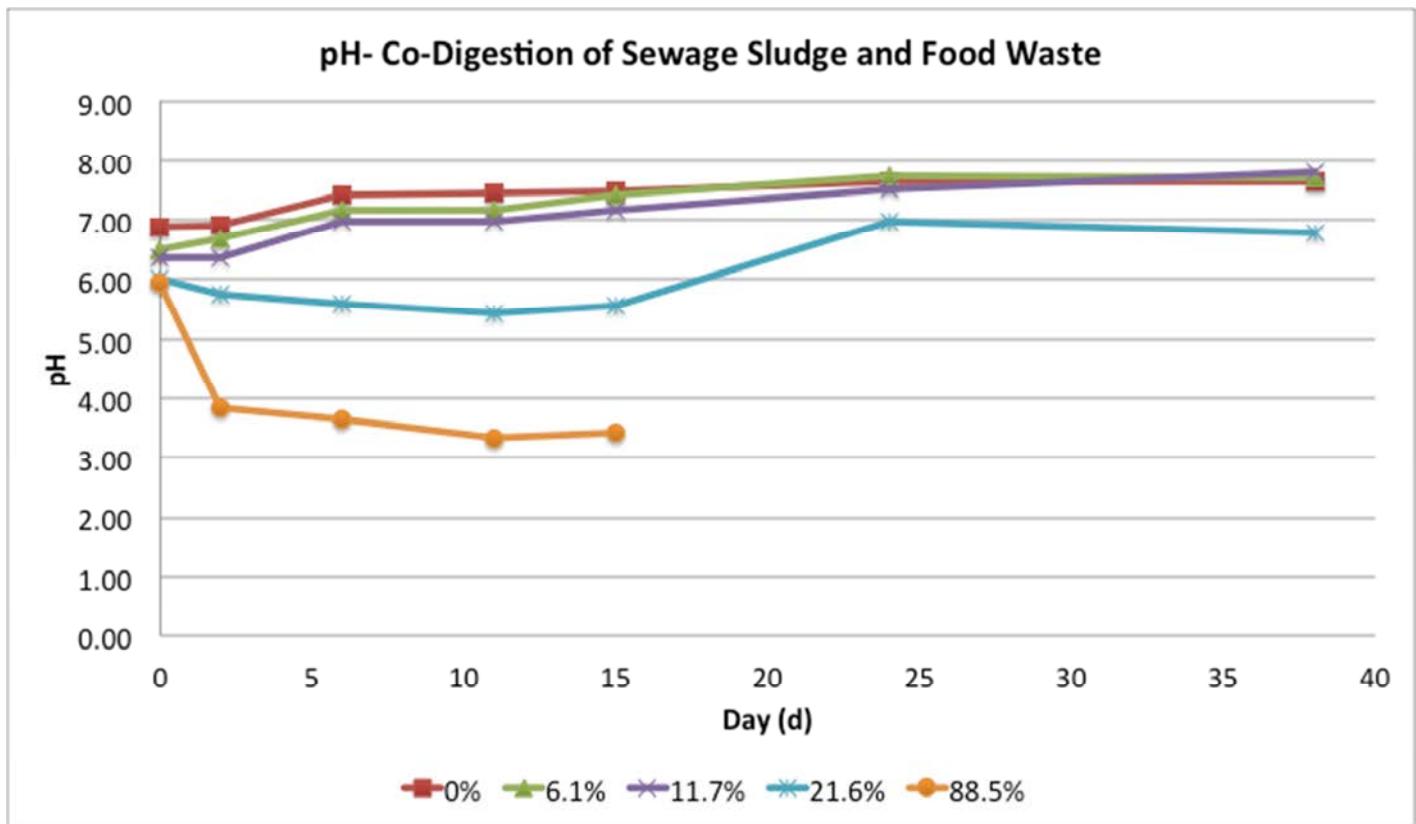

Figure 3
Batch Digestion pH

The alkalinity of the samples at the start of the experiment (time zero) varied from 2,000 milligrams per liter (mg/L) to 4,000 mg/L. The samples with lower ratios of FW had higher alkalinity in comparison to the higher ratios of FW. Similarly, the pH of the reactors with a higher content of FW was lower (pH = 6) in comparison to reactors with a lower content of FW (pH = 6.5-7.0) at time zero. The alkalinity of the reactor containing 88.5% FW was depleted within two days from the start of the experiment. As a result, the pH of the reactor was reduced to less than 4 and the biological reaction ceased. The pH and alkalinity of the reactor containing 21.6% FW initially decreased. After 15 days, both the alkalinity and pH increased. The laboratory data supporting Figures 2 and 3 and others described hereinafter for the batch digestion study are contained in Appendix A.

Referring to Figure 4, initial TS concentrations in the digesters varied between 3 to 4% in all samples but the 88.5% FW, which was about 9%. The reactors with higher FW ratios had higher TS concentrations. Through day 38, all digesters but the 88.5% FW showed a decrease in TS to about 2% due to VS reduction. The reactor with 88.5% FW digester decreased to about 7% within two days due to rapid biological decomposition that resulted in a decrease of the alkalinity and pH in the reactor. Within the next 9 days the TS gradually decreased to about 6.5%, and after about 15 days the TS increased to 8% in the 88.5% FW digester. It is safe to assume that, in the digester with the 88.5% FW, the depletion of alkalinity and reduction of pH to about 4 resulted in the cessation of biological reactions after about 10 days.

Figure 4
Batch Digestion Total Solids

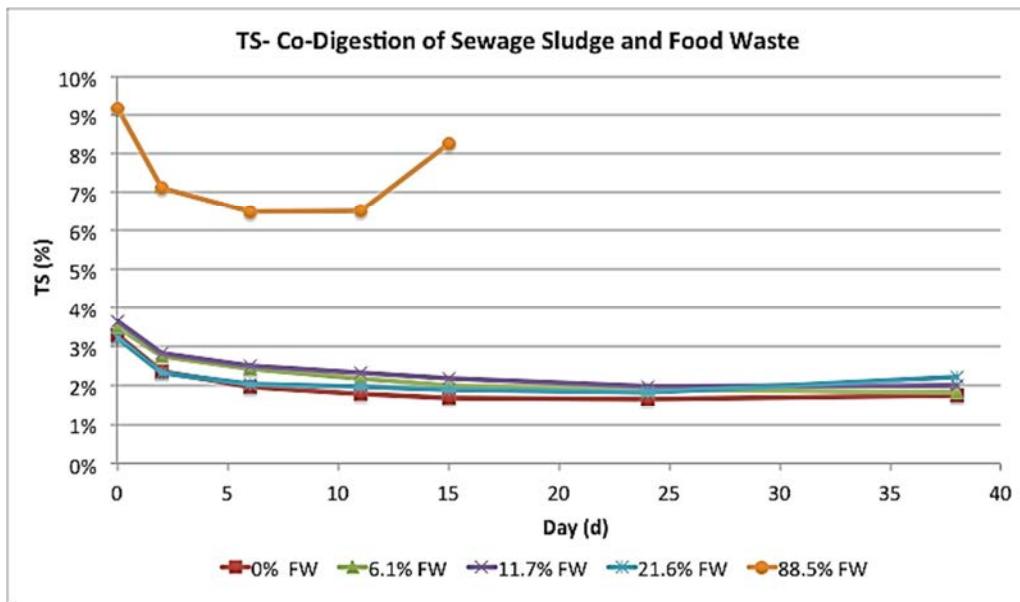

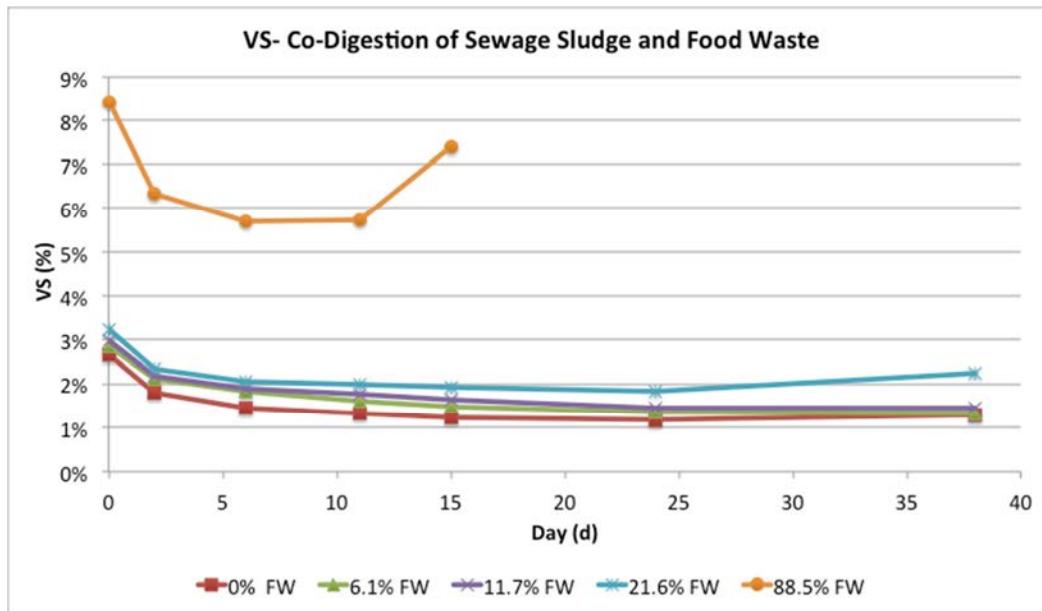

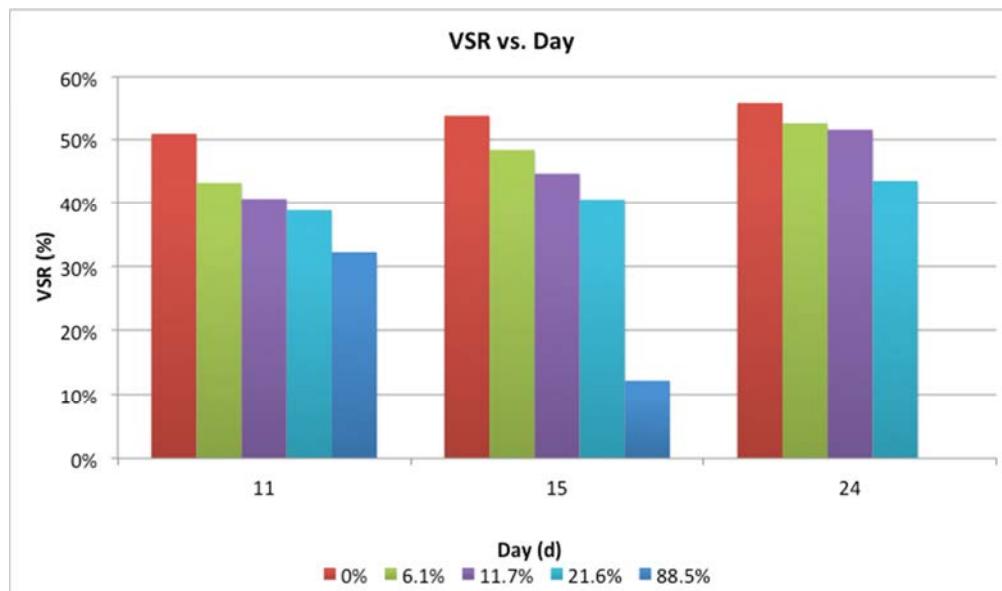

Figure 5 presents VS data for the study. Except for the 88.5% FW digester, initial VS concentrations were slightly higher than the control digester, and all were within about 2.5 to 3.3%. By day 38, VS concentrations were about 1 to 1.5% for the control, 6.1% and 11.7% FW digesters, and just above 2% for the 21.6% FW digester. The VS concentration for the 88.5% FW digester started out at about 8.5%, decreased to just under 6% on day 11, and then increased to about 7.3% on day 15, indicating failure of the digester.

Figure 5
Batch Digestion Volatile Solids

Percent VSR for the digesters on days 11, 15 and 24 is shown in Figure 6. VSR in the control samples was greater than 50%. VSR in all other reactors except the 88.5% FW reactor ranged from 40 to 55 percent. The percent VSR was inversely proportional to the initial FW content or VS/TS ratio. The 88.5% FW digester exhibited about a 32% reduction on day 11 and 12% reduction on day 15 – another indication of digester failure.

Figure 6
Batch Digestion Volatile Solids Reduction

To investigate nutrient load impacts in the digester side-stream, the study included sample analysis for soluble total nitrogen (STN) and soluble phosphate (SPO_4) (Figures 7 and 8, respectively).

Figure 7
Batch Digestion Soluble Total Nitrogen Concentration

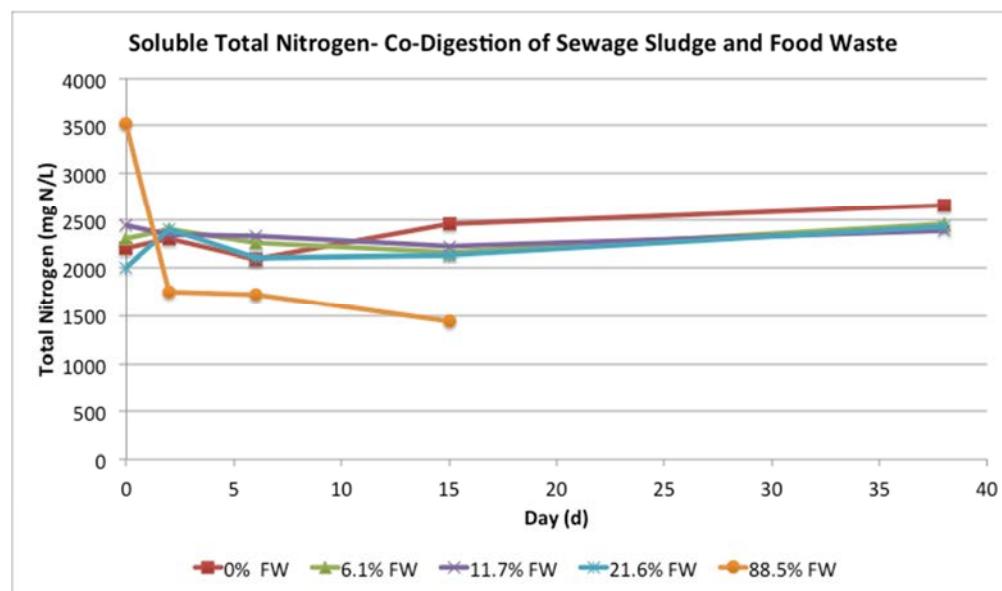

Figure 8
Batch Digestion Soluble Phosphate Concentration

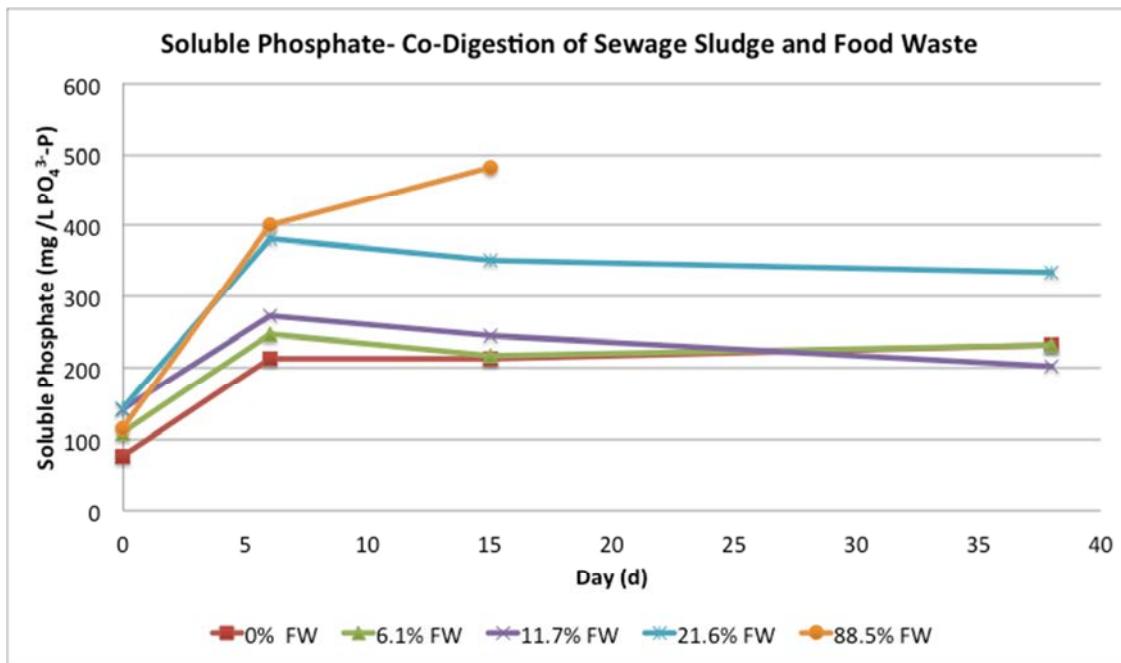

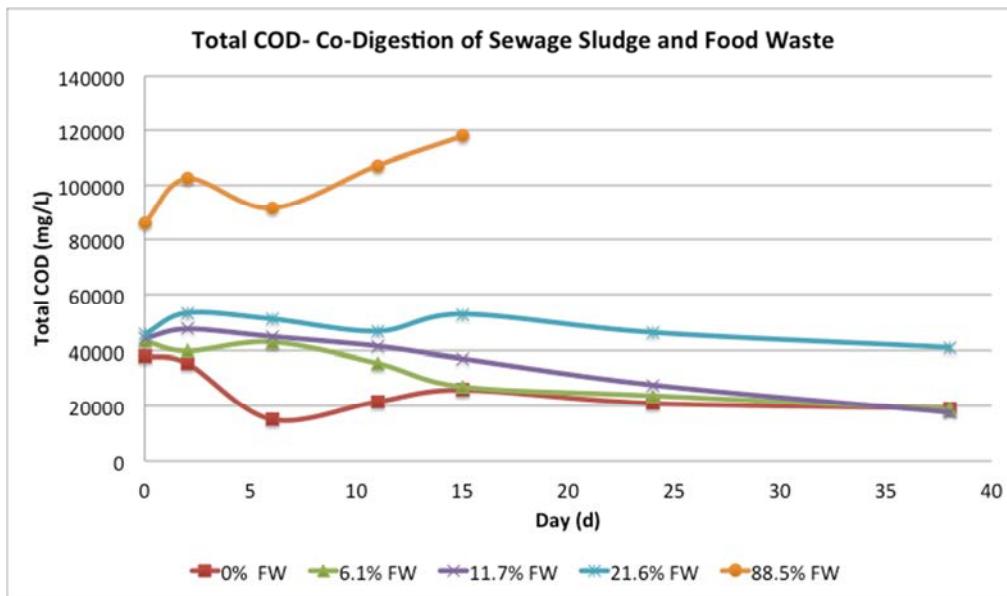

Figure 7 indicates similar results again for all but the 88.5% FW digester, with STN concentrations in the range of 2,000 – 2,700 mg/L through day 38. The 88.5% FW digester started with an STN concentration of 3,500 mg/L, which dropped to about 1,500 mg/L by day 15. Initial SPO_4 concentrations in all samples ranged from about 75 – 150 mg/L, and then increased to between 200 – 400 mg/L on day 6, with the higher FW percent samples having the higher values. The 88.5% FW digester SPO_4 concentration continued to increase to close to 500 mg/L on day 15, whereas the other digesters showed a slight decline in this nutrient through day 38. Based on these results, it does not appear that FW has a significant impact on STN and SPO_4 concentrations in the digester side-stream.

More detailed discussion of the impact of the FW/SS co-digestion on the nutrient concentrations in the digester side-streams are presented later in the semi-continuous co-digestion study.

Figure 9 displays COD concentrations for the various digesters. The initial concentrations range from about 4,000 – 5,000 mg/L, except for the 88.5% FW digester, which was between 8,000 and 9,000 mg/L. The 88.5% FW digester increased in COD concentration to about 12,000 mg/L by day 15, and the others showed some variability until day 15, and then a decreasing trend to day 38.

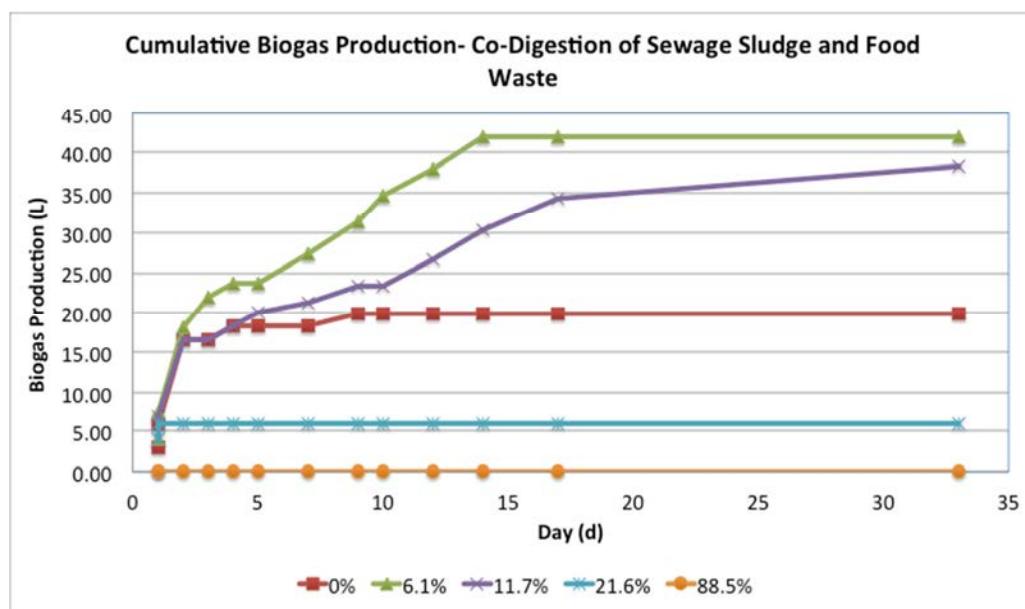

On day 38, the 21.6% FW digester had a COD concentration of 4,000 mg/L, and the control, 6.1 % and 11.7% FW digesters all had a concentration of about 2,000 mg/L. Thus, through the 11.7% FW concentration, there appeared to be good COD reduction – about 50%, but the higher FW concentration (21.6% FW reactor) achieved little or no COD reduction in comparison to the initial concentration.

Figure 9
Batch Digestion Total COD

Cumulative biogas production for the digesters is shown in Figure 10. Biogas production in reactors containing 6.1% and 11.7% FW was approximately twice the biogas production in the control reactor after 38 days. Biogas production in the 21.6% FW reactor was much less in comparison to the control. This was attributed to problems with the biogas collection in the 21.6% FW reactor. The 88.5% FW reactor produced no biogas, indicating its failure. These results indicate that FW mixed with SS may be more productive than SS alone for biogas generation.

Figure 10
Batch Digestion Biogas Production

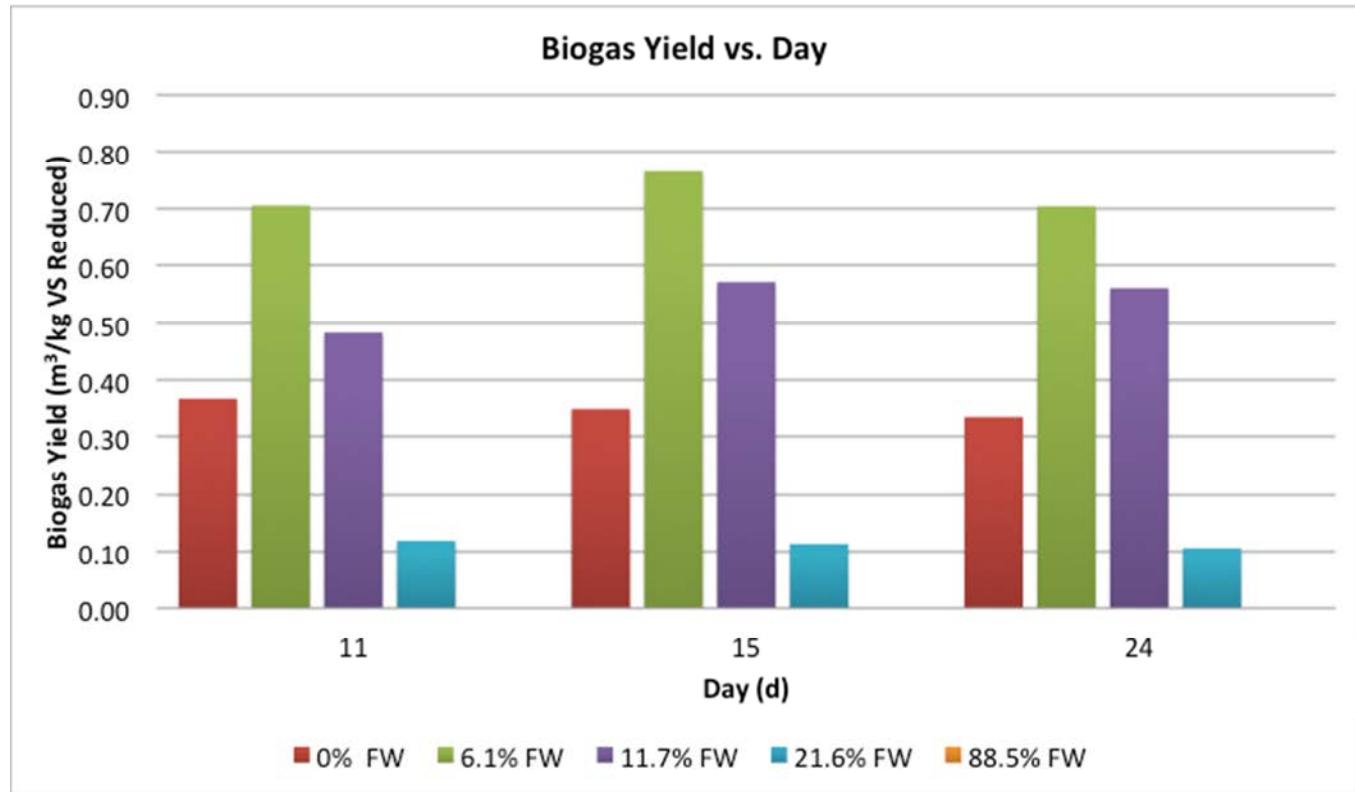

To support the previous statement, Table 8 shows biogas production per unit VS loading, and indicates improved biogas yields for the 6.1%, 11.7% and 21.6% FW digesters as compared to the control digester.

Table 8
Biogas Generation Yields

% FW	L/g VS Fed	Ft ³ /lb VS Fed
0	0.27	4.38
6.1	0.35	5.53
11.7	0.33	5.26
21.6	0.30	4.78
88.5	0	0

Figure 11 presents biogas yield in terms of volume of biogas produced vs. weight of VSR for days 11, 15 and 24. This figure demonstrates the superior biogas production achieved by the 6.1% and 11.7% FW digesters as compared to the control digester.

Figure 11
Batch Digestion Biogas Yield

Summary

The bench-scale batch co-digestion study was conducted using various ratios of FW to SS including 0, 6.1%, 11.7%, 21.6% and 88.5%. The co-digestion study was continued for 38 days under mesophilic temperature conditions. The results indicated that the co-digestion of

FW and SS using the above-mentioned ratios is feasible except at 88.5% FW. The 88.5% co-digestion reactor failed within the initial 10 days of operation due to the depletion of alkalinity which caused the pH to drop to a value of 4. No extraneous sources of alkalinity were added to the digesters. In the digesters using 6.1%, 11.7% and 21.6% FW, efficient TS and VS reduction and biogas production were achieved. The increase in STN and SPO_4 concentration in the side-streams due to the FW addition was not significant.

It should be noted that the bench-scale batch digestion study was designed to evaluate the co-digestibility of FW and SS from DITP under various FW/SS combinations. The ratios of FW to feed sludge used in this batch study were greater than the ratios intended to be used at DITP in the future. Therefore, the results obtained from the batch study would be associated with extreme operating conditions. The batch study, however, served as a learning tool for the methods, procedures and FW percentages to use in the subsequent semi-continuous bench-scale study, which more closely matched digester operation at DITP.

5.0 Phase III – Bench-Scale Semi-Continuous Study

Semi-Continuous Study Setup

The semi-continuous anaerobic digestion study began on February 22, 2013 with the feeding of various combinations of FW and SS along with seed sludge from DITP into six 4-liter digesters. The digester setup was similar to that for the batch study. Each digester was closed with a rubber stopper through which two-glass tubing sampling ports were pierced. The first piece of glass tubing was used as a sampling port for biogas, through which the biogas was collected into a plastic gas bag. The second sampling port was used to feed sludge and withdraw digested sludge for measurement.

Feeding occurred after wasting each day, five times per week. The SRT of the system was maintained at 28 days for the first 73 days of the study and then switched to 22 days for the rest of the 150-day study period to more closely match the 18-day SRT at DITP. Approximately 200 - 250 mL of material was fed and wasted during each feeding/wasting event, based on SRT. DITP primary and secondary sewage sludge was delivered overnight on ice, weekly, and kept in a constant temperature room (4°C) until feeding.

FW was collected at the start of the semi-continuous phase from Waste Management, Inc. and kept in a constant temperature room (4°C) until feeding as well. Required portions of FW and SS for each digester were combined daily, brought to 37°C , and fed to the digesters. Each digester was seeded with 2 liters of field-combined primary and secondary anaerobically digested sewage sludge collected from DITP.

As during the batch digestion study, all 6 digester reactors were stored in a temperature-controlled room that was maintained at a temperature of 37°C to simulate mesophilic conditions in the anaerobic digesters at DITP. The digesters and contents were mixed by a constructed shaker, at approximately 100 rpm for the duration of the study.

Table 9 presents the breakdown of the feed composition for the six reactor/digesters.

Table 9
Semi-Continuous Digestion Setup

Digester ID	Feed Composition (FW/FS)	Food Waste (FW)			Feed Sludge (FS)			
		(w/w)	TS (%)	Feed (L)	Mass (%)	TS (%)	Feed (L)	Mass (%)
R1	100% Feed Sludge		15.0%	0.000	0%	5.2%	0.250	100%
R2	100% Feed Sludge		15.0%	0.000	0%	5.2%	0.250	100%
R3	10% Food Waste		15.0%	0.010	10%	5.2%	0.240	90%
R4	20% Food Waste		15.0%	0.020	20%	5.2%	0.230	80%
R5	20% Food Waste		15.0%	0.020	20%	5.2%	0.230	80%
R6	50% Food Waste		15.0%	0.065	50%	5.2%	0.185	50%

As indicated in the table, the FW percentages in the feed to the digesters varied from zero in control digester R1 (all DITP feed sludge and no FW) to 50% in digester R6. One digester (R3) was run with a FW feed rate of 10%, and two others (R4 and R5) were run with the FW feed rate of 20%. Digester R2 was initially fed with 100% FW but subsequently failed about 50 days into the study and was then converted to a second control reactor with 100% feed sludge. All FW percentages in Table 8 are based on dry weight of solids in the feed to the digester, as opposed to dry weight of solids in the digester, which was how the FW percentages were defined for the batch study.

Analytical Methods

Biogas and digested sludge samples of the reactors were taken twice a week and analyzed for methane content, COD, pH, total alkalinity, volatile acid alkalinity (VAA), TS, VS, STN, SPO₄, and CST. Table 10 lists the study parameters and analytical methods used during the study. Methane content of the biogas was measured by gas chromatograph (GC) (Agilent Technologies 6890N, CA, USA) with a thermal conductivity detector (TCD) equipped with a PLOT-HQ column. COD, pH, total alkalinity, VAA, and TS/VS were determined according to *Standard Methods for the Analysis of Water and Wastewater* (APHA, 1995). To analyze for STN and SPO₄, sludge samples from the reactors were centrifuged at 10,000 rpm for 40 minutes. The supernatant was passed through a Whatman glass fiber filter (0.45 µm) and the filtrate was analyzed using HACH kits (TNT 845 and TNT 828).

Semi-Continuous Study Results and Discussion

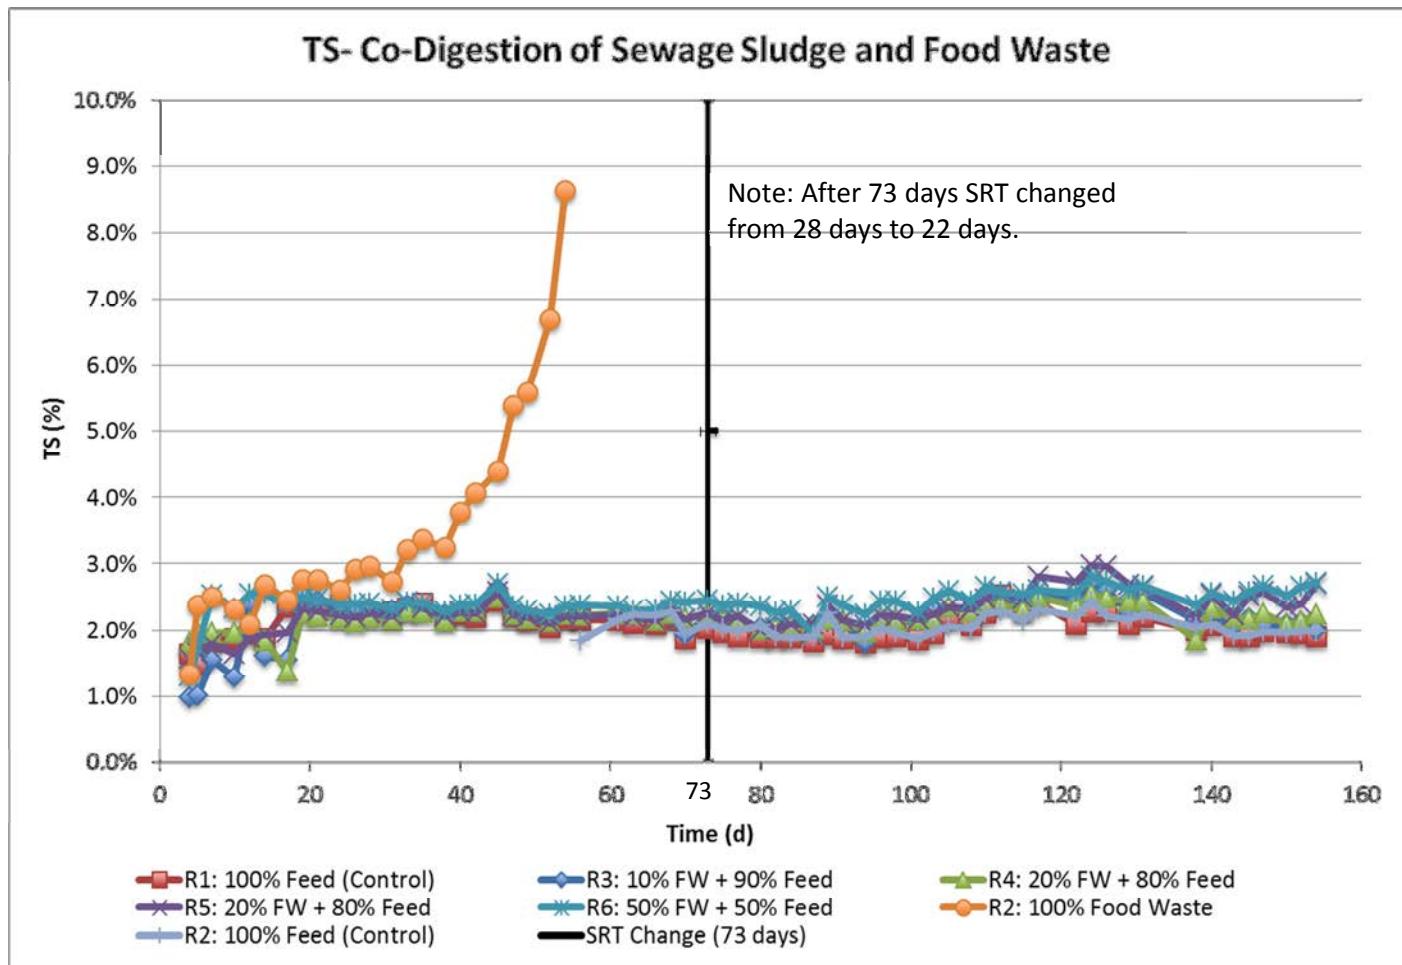

Solids loading criteria for the 6 digesters are presented in Table 11. Digesters R1 and R2 were used as control digesters. These solids loading rates are similar to the loading rates used at DITP. As indicated, with the addition of 10% FW to the test digester R3, the VS loading rates increased by 9.8% over the loading rate in the control digesters. When 20% FW was added in R4 and R5, the VS loading rate increased by 22%, and when 50% FW was added in R6, the VS loading rate increased by almost 66% over the VS loading rate in the control digesters. Table 11 also shows the corresponding values for DITP based on an average SRT of 18 days.

Table 11
Semi-Continuous Feed Solids and Volumetric Loading Rates

FW/(FW+SS)	Average TS	Average VS	VS/TS	VS loading	VS loading	VS/VS Control	
	(%)	(%)	(%)	(%)	(kg VS/m ³ -d)	(lb VS/ft ³ -d)	(% increase)
R1	0	5.0	4.1	82.0	2.56	0.16

R3	10	5.4	4.5	83.3	2.81	0.18	9.8
R4	20	5.9	5.0	84.7	3.13	0.20	22.0
R5	20	5.9	5.0	84.7	3.13	0.20	22.0
R6	50	7.9	6.8	86.1	4.25	0.27	65.9
DITP		5.2	4.4	84.6	2.34	0.15	

Figure 12 presents a graph of the TS concentration in each digester over the 150-day study period. As shown, after the first 20 days, the TS concentrations stabilized to average between 2.0 to 2.5%. On day 73, the targeted SRT of all digesters changed from 28 days to 22 days, as noted on the figure. As can be seen from the graph, this change in SRT had no significant impact on the TS concentration in the digesters. The typical average value for TS in the anaerobic digesters at DITP is 2.5%. The curve for the R2 digester with 100% FW represents the TS results during the first 50 days of the study prior to its failure. As previously described, this digester was subsequently converted to a second control digester. The laboratory data supporting Figure 12 and others described hereinafter for the semi-continuous digestion study are located in Appendix B.

Figure 12
Semi-Continuous Total Solids Concentration

VSR efficiency for the digesters during the 28-day SRT period and 22-day SRT period is shown in Table 12. This table includes the results for both the percentage of VSR compared to VS loading as well as VSR compared to VS percentage. Graphical representations of these results for the 150-day study period are shown in Figures 13 and 14. At DITP, the VSR efficiency by VS loading has averaged 60.5%, while the VSR by VS percent has averaged 62.3%. This study found that the VSR efficiency by VS loading increased with FW addition to the sludge feed. As indicated in Table 12, VSR efficiency by VS loading for the 28-day SRT increased by 18% in the R3 digester, 5% in R4, 8% in R5, and 10% in R6. VSR efficiency by VS loading for the 22-day SRT increased by 2% in the R3 digester, 6% in R4 and R5, and 18% in R6. The corresponding values for DITP based on an 18-day SRT are also presented in Table 12.

Table 12
Volatile Solids Reduction Efficiency

FW/(FW+SS)	28 day SRT		22 day SRT		
	VS Reduced by Loading (%)	VS Reduced by Percent (%)	VS Reduced by Loading (%)	VS Reduced by Percent (%)	
	(%)	(%)	(%)	(%)	
R1	0	66.1%	60.4%	64.8%	57.2%
R2	0	65.6%	63.3%	64.8%	58.9%
R3	10	77.7%	75.1%	66.0%	61.4%
R4	20	69.0%	62.3%	69.0%	60.7%
R5	20	71.0%	63.2%	68.8%	61.6%
R6	50	72.2%	62.2%	76.4%	62.4%
DITP				60.5%	62.3%

Figure 13

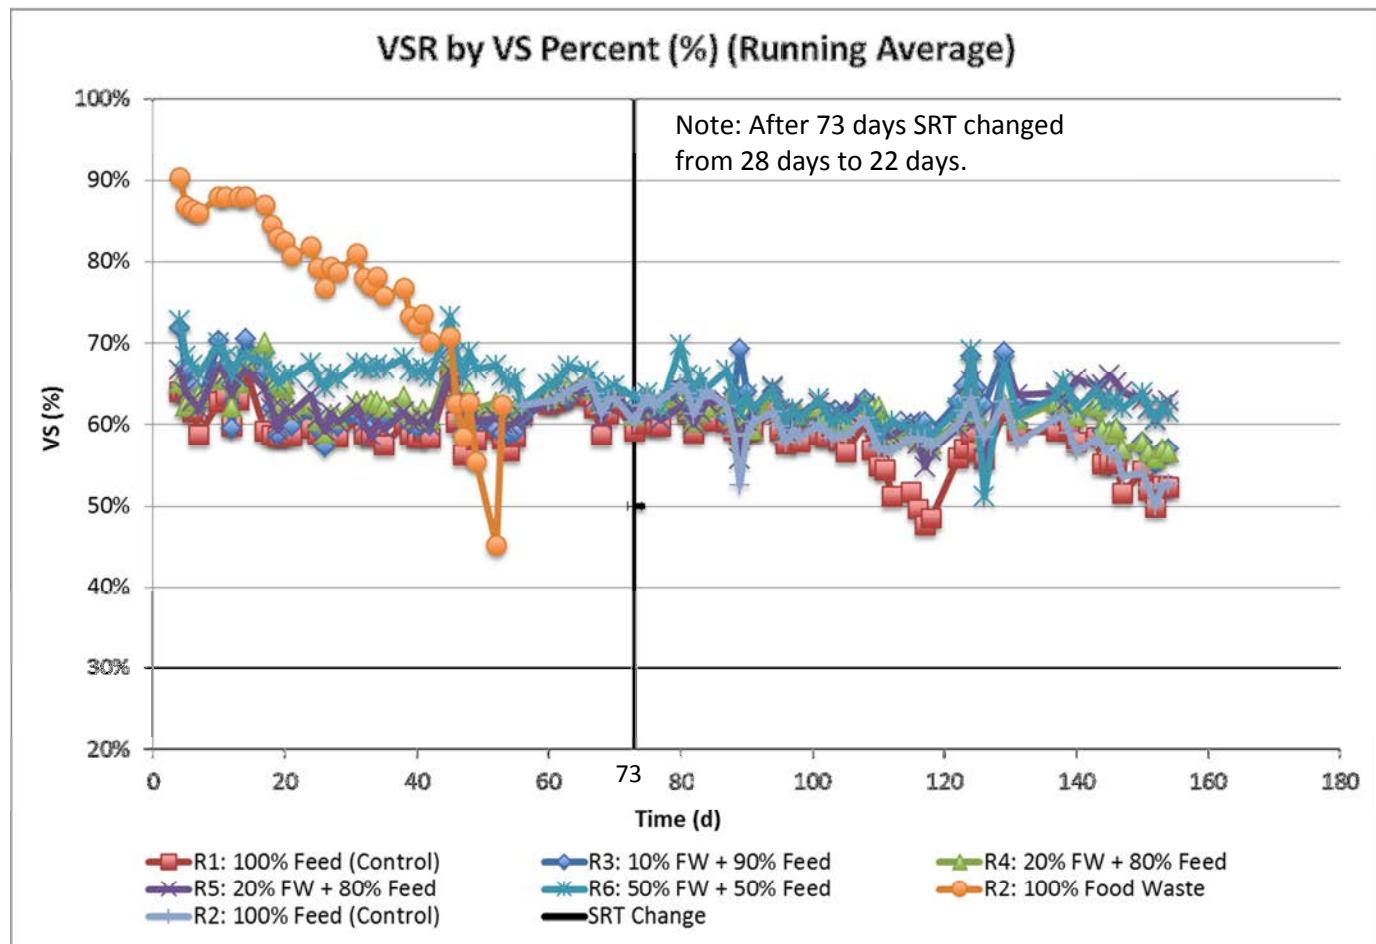

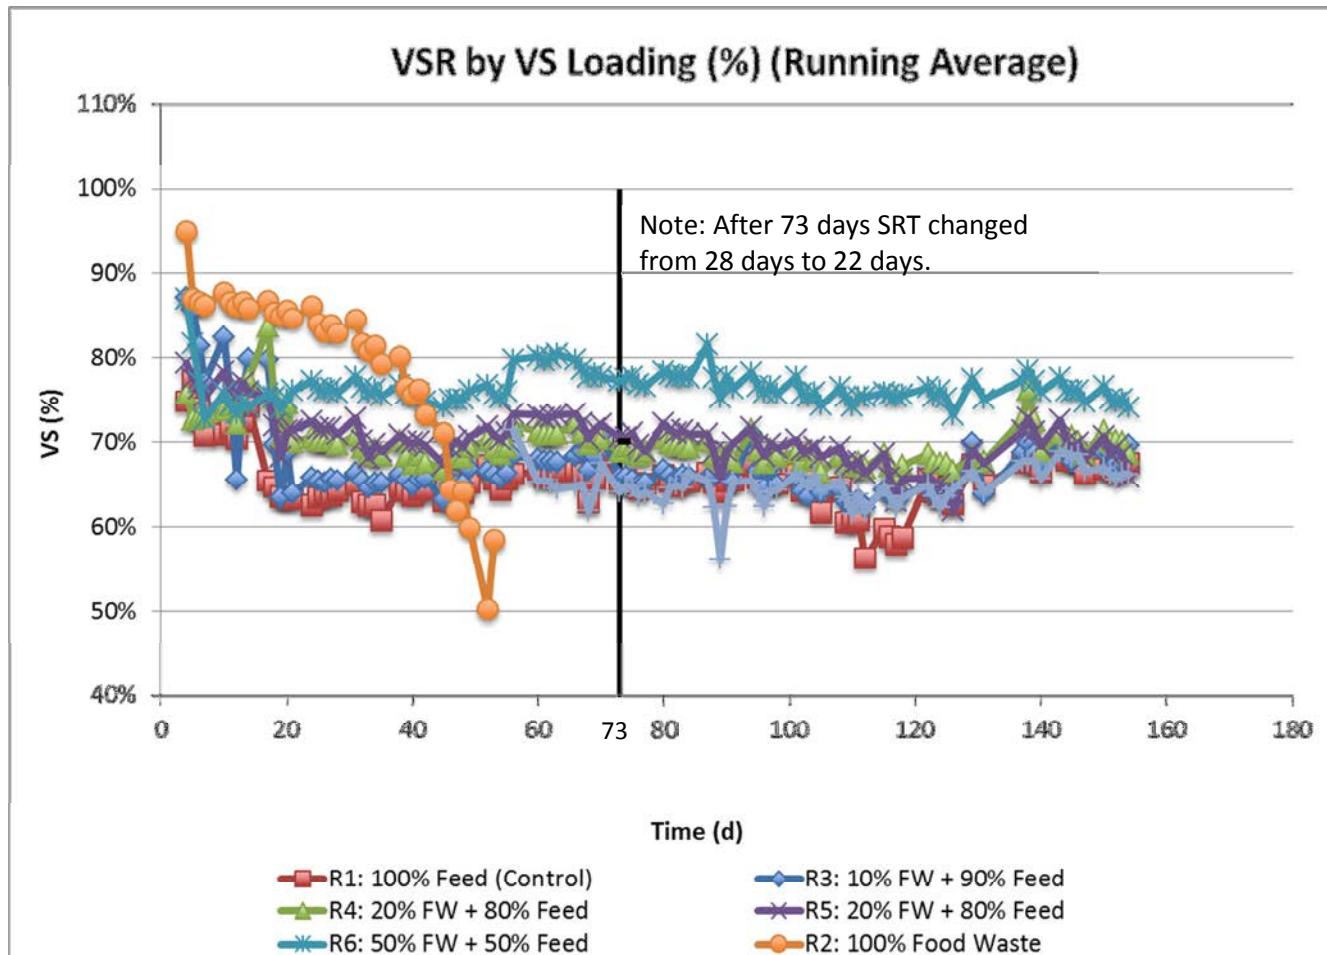

Figure 14

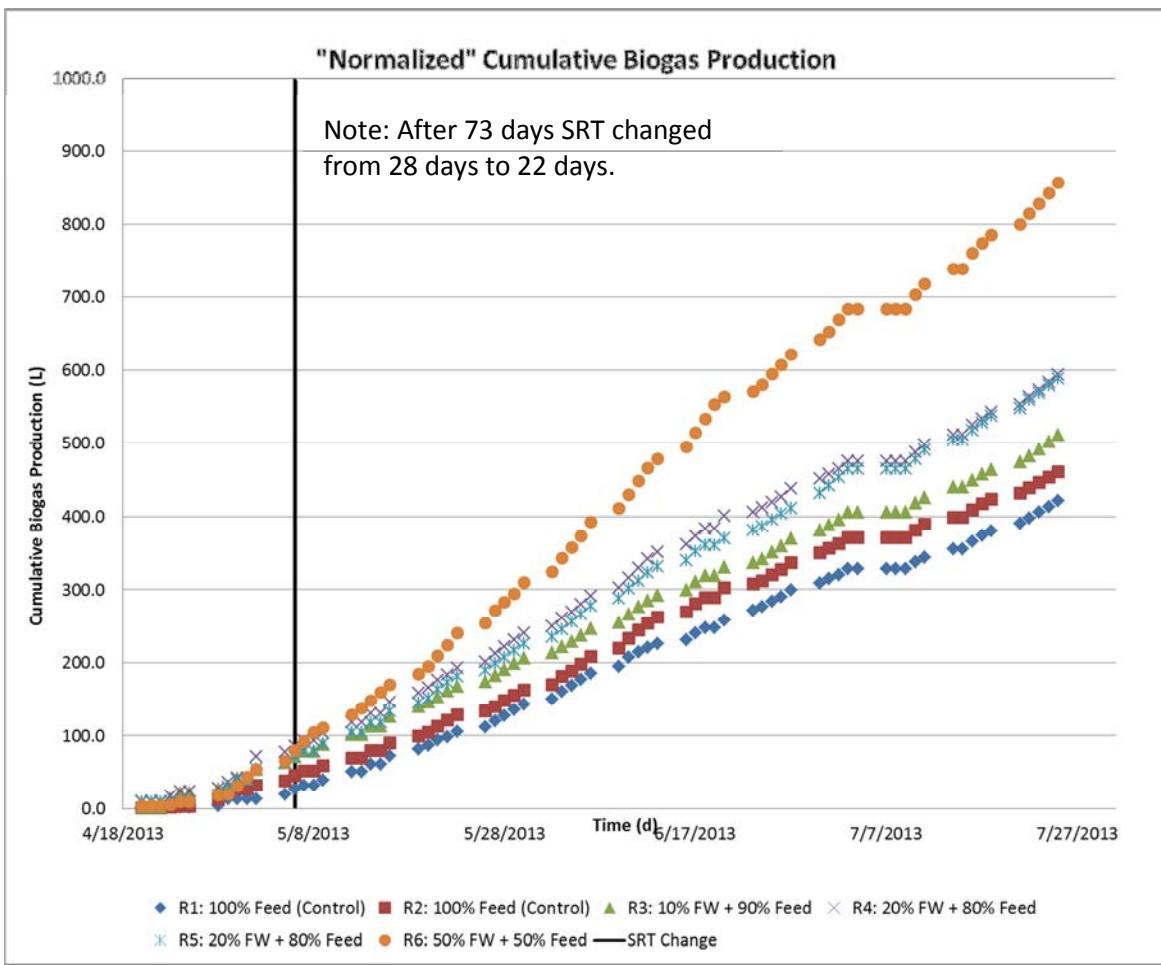

Biogas production in terms of volume (liters) for the digesters is shown in Table 13. For the two control digesters the average biogas production was about 4.0 liters per day. Biogas production in the remaining test digesters increased with increasing percentages of FW feed. As indicated, biogas generation increased by 22% in the R3 digester, 39% in R4 and R5, and 97% in R6. The “normalized” graph of the cumulative biogas production versus time is presented in Figure 15 and shows the increasing biogas production resulting from increases in FW.

Table 13
Biogas Generation Rates

	FW/(FW+SS) Average for 22-d SRT(since May 6)	
	(%)	(L/d)
R1	0	3.7
R2	0	4.2
R3	10	4.8
R4	20	5.6
R5	20	5.4
R6	50	7.8

Figure 15

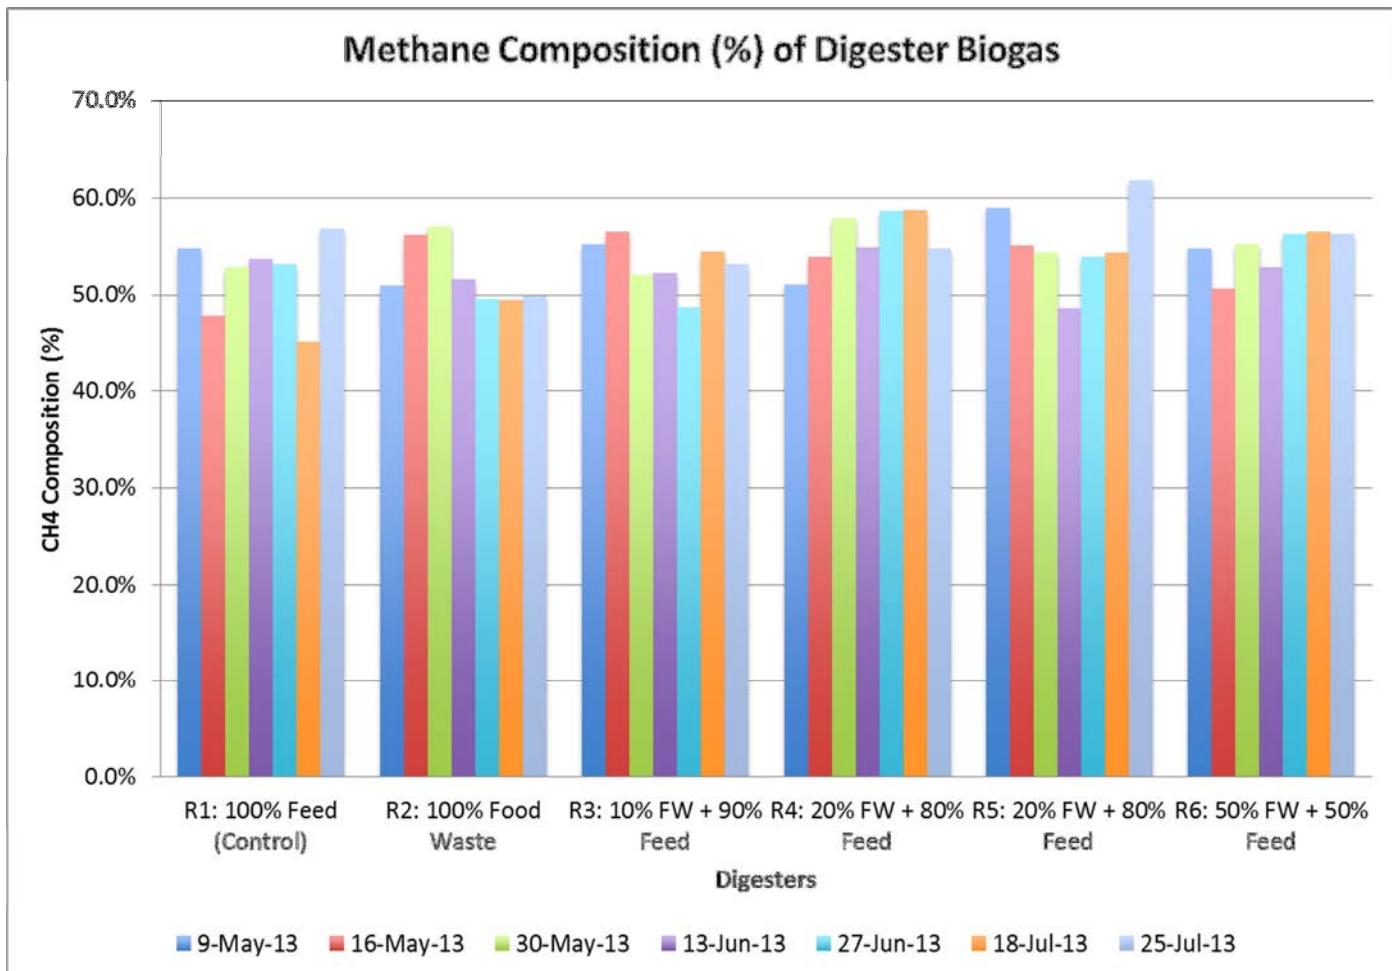

The study results for biogas yield in terms of volume of biogas produced per VS destroyed is presented in Table 14. For the control digesters, the biogas yield averaged 13.3 ft^3 per pound of VS destroyed. While this value is lower than the average biogas yield at DITP (17.7 ft^3 per pound of VS destroyed) the study results do indicate that biogas yields can be increased by adding increasing amounts of FW up to 50%.

Table 14
Biogas Generation Yields

Average Gas Yields for 22-d SRT(since May 6)					
FW/(FW+SS)		(L/g VS Fed)	(ft ³ /lb VS Fed)	(L/g VS Destroyed)	(ft ³ /lb VS Destroyed)
R1	0	0.51	8.1	0.76	12.2
R2	0	0.60	9.6	0.90	14.4
R3	10	0.66	10.5	0.96	15.3
R4	20	0.70	11.2	0.96	15.4
R5	20	0.65	10.5	0.90	14.4
R6	50	0.66	10.6	0.82	13.1

The composition of the biogas produced during this study in terms of methane concentration is shown in Figure 16. Overall, methane concentrations averaged over 50% in all digesters.

Figure 16

Figures 17 and 18 display pH, alkalinity, and VAA sampling results during the semi-continuous phase of the study for the various FW/SS feed combinations. As these graphs indicate, the values in the control digesters (R1 and R2) were similar to the values measured in the digesters with varying amounts of FW. The pH and alkalinity values in the initial R2 digester with 100% FW feed also tracked the values in the other digesters for the first 40 days, but then changed dramatically indicating the failure of that test digester due to accumulation of volatile acids and depletion of alkalinity, which decreased the pH. As can be seen from the graphs, when the target SRT changed from 28 days to 22 days, the pH became more stable in the digesters at approximately 7.4. The alkalinity and VAA also slightly decreased after the change in SRT.

Figure 17

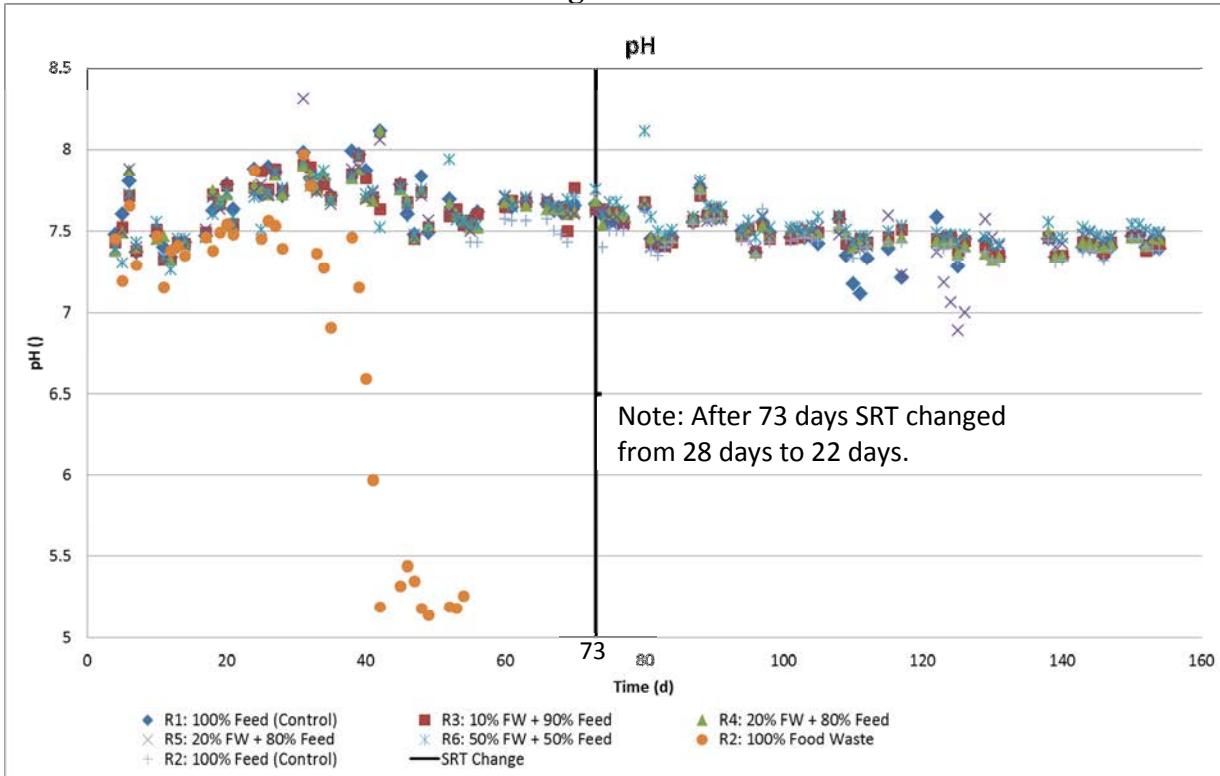

Figure 18

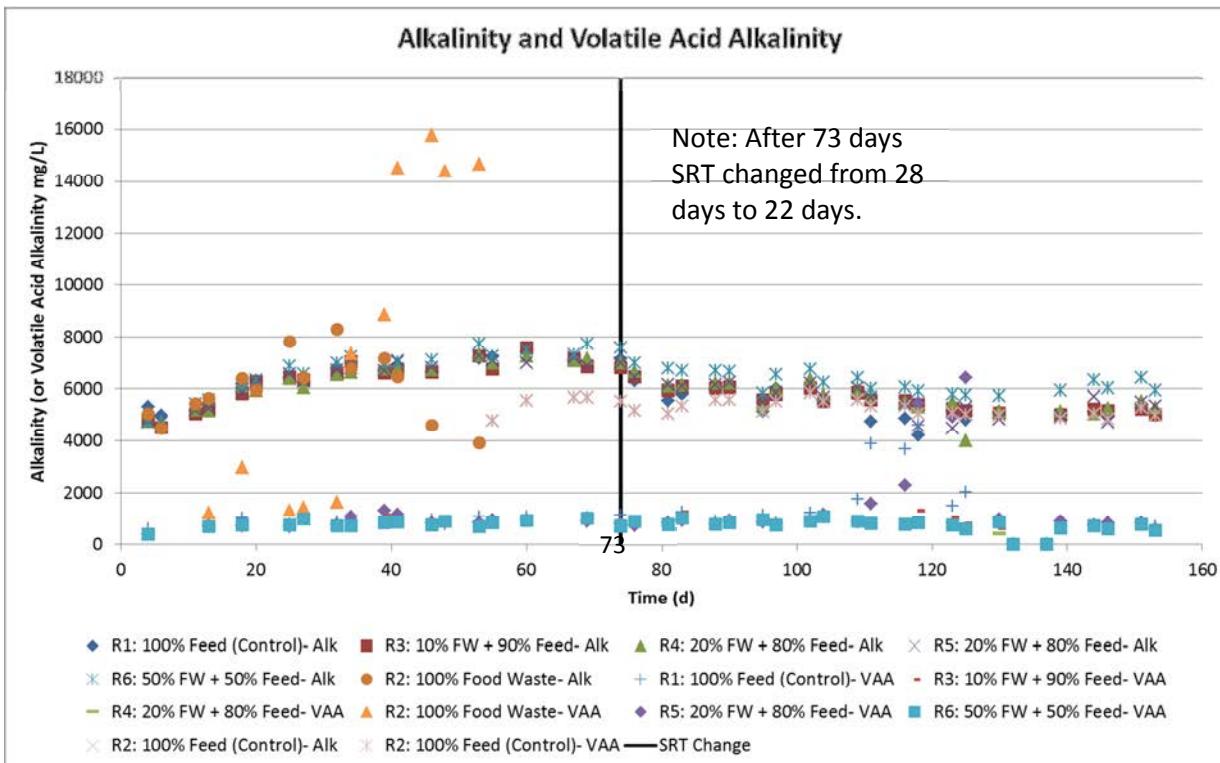

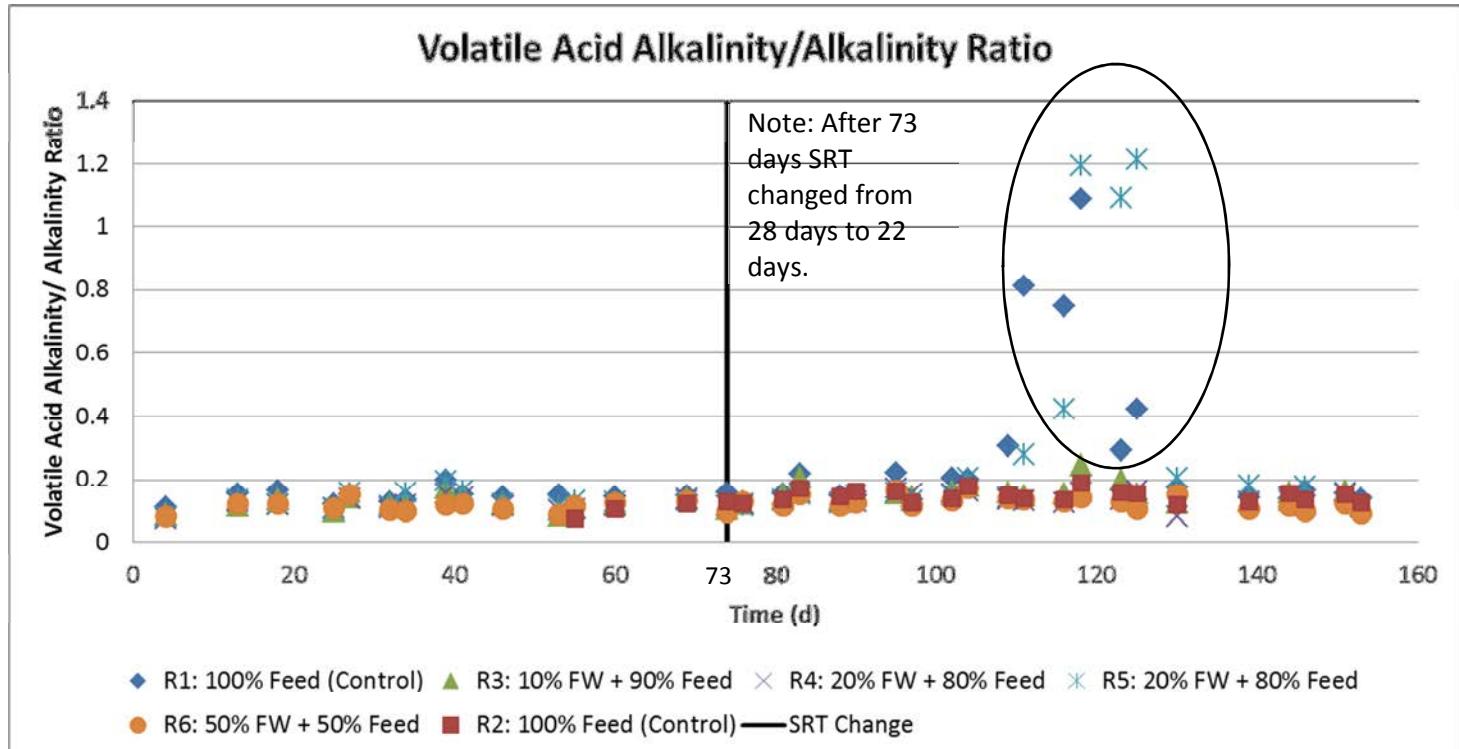

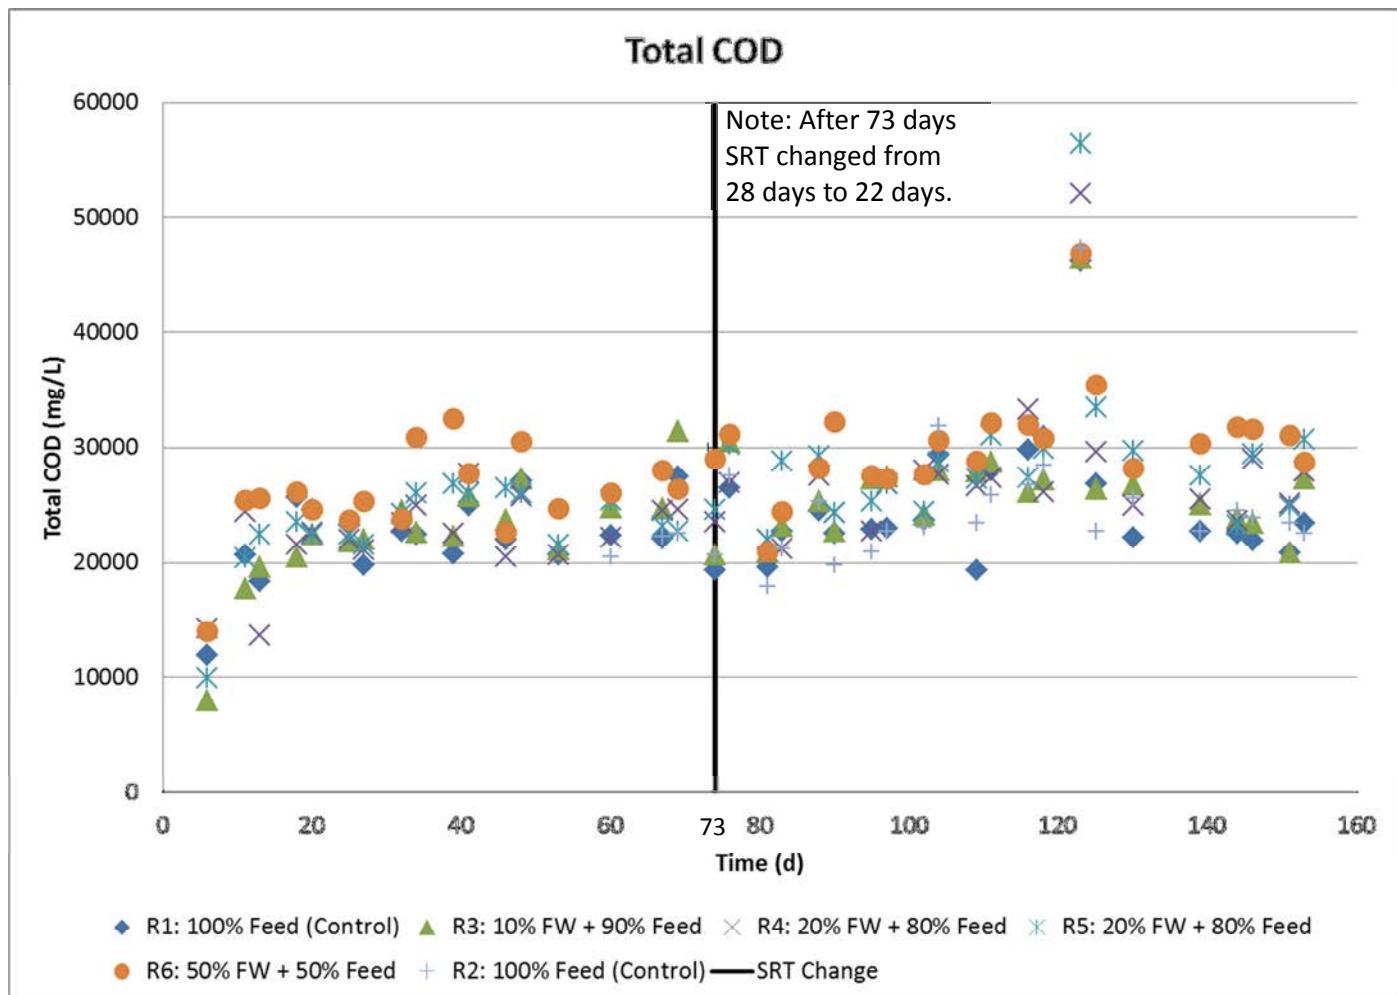

Figure 19 shows the relationship of the VAA to alkalinity ratio versus time for the various FW/SS feed combinations. As shown, there was good correlation between the parameters except for the indicated (circled) short time period when clogging and air injection caused problems in digesters R1 and R5. The change in SRT did not have a significant impact on the VAA to alkalinity ratio.

Figure 19

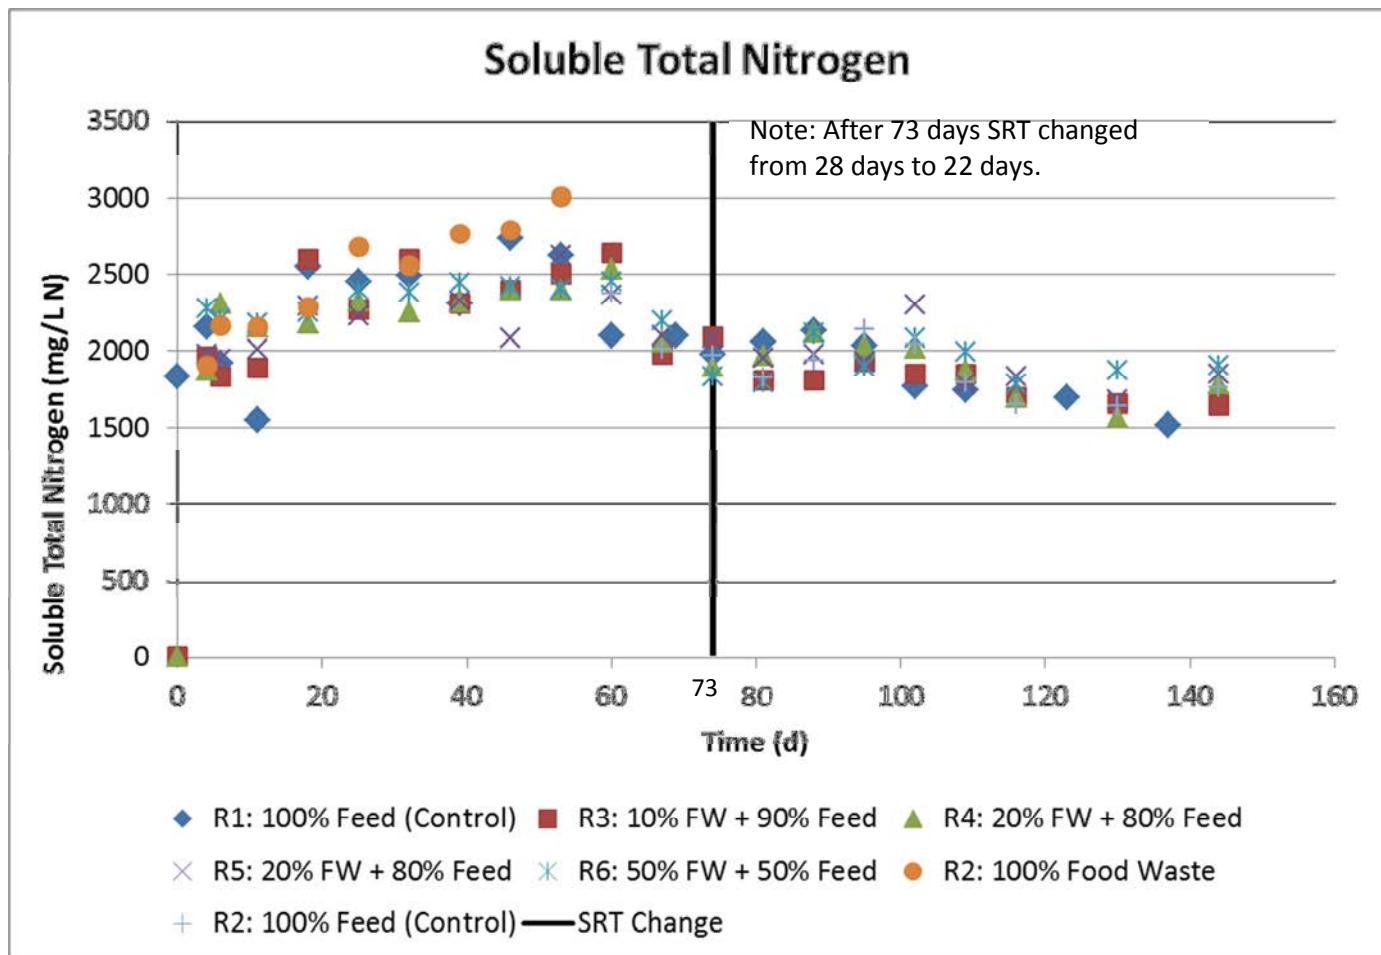

The results of the semi-continuous anaerobic digestion study in terms of the effects on COD are presented in Figure 20. Overall, the results for the two control digesters and the digesters fed with varying percentages of FW remained fairly consistent over the 150-day duration of the study. CODs in the control digesters typically averaged around 21,000 mg/L throughout the study while the CODs for the FW digesters generally increased with increasing percentages of FW. Reactor R6 with a FW feed of 50% generated the highest COD values, starting out the study at around 25,000 mg/L and finishing at about 30,000 mg/L. As can be seen from the graph, COD levels were slightly higher during the 22-day SRT time due to less digestion time in the digesters.

Figure 20

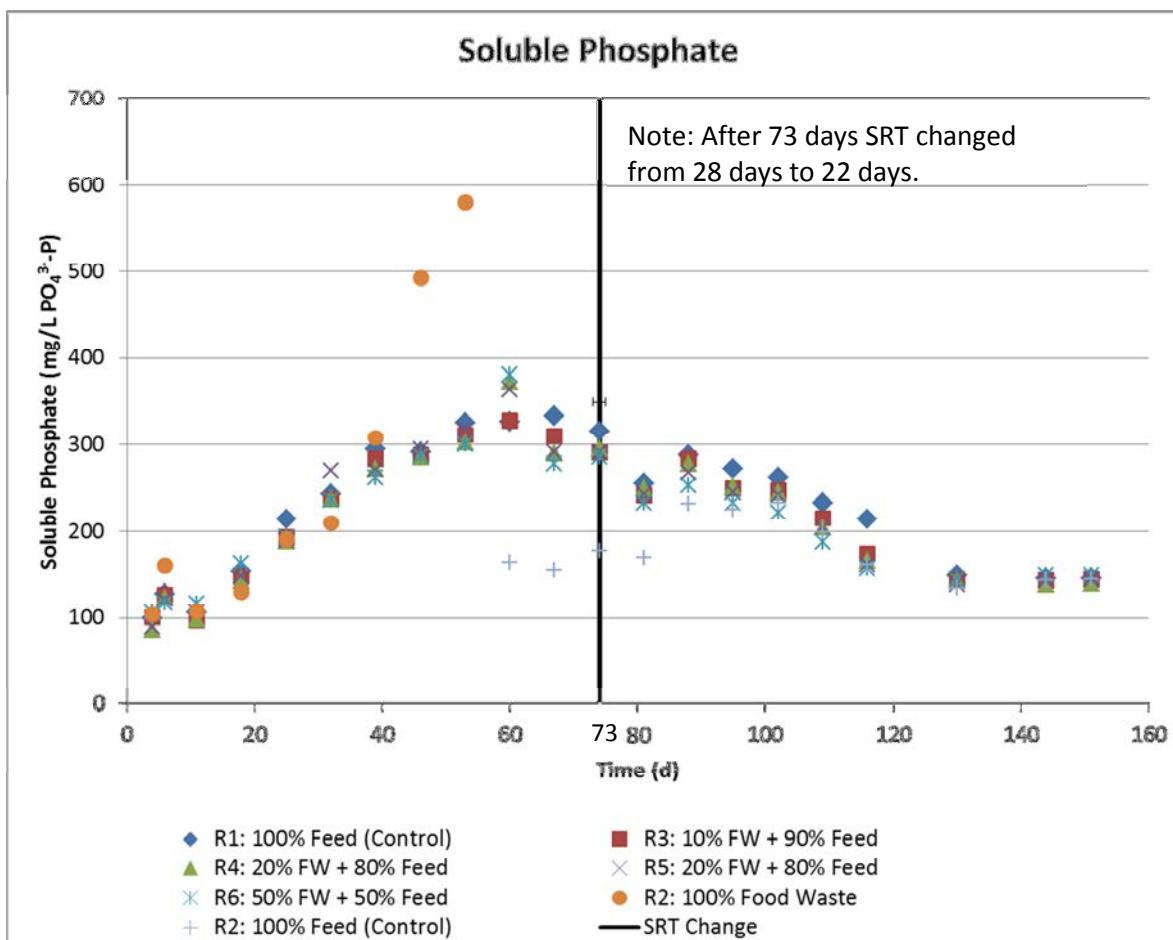

Nutrient load impacts associated with nitrogen and phosphorus are presented in Figures 21 and 22, respectively. The results for STN versus time shown in Figure 21 indicate that all digesters followed a similar pattern, starting out with values around 2,000 mg/L and then gradually increasing to around 2,500 mg/L around day 40. Following day 60, the STN values in all digesters gradually decreased to values between 1,500 to 1,900 mg/L by the end of the 150-day study. The change in SRT from 28 days to 22 days resulted in lower STN concentrations due to the decreased time to break down the biosolids in the digesters.

Figure 21

The results for SPO₄ versus time presented in Figure 22 indicate all digesters trending in a similar fashion. As shown, each digester started out with an SPO₄ value of about 100 mg/L that increased to around 300 mg/L after 60 days, except for the 100% FW digester, whose SPO₄ value rose to almost 600 mg/L prior to failure. The change in SRT from 28 days to 22 days resulted in decreased SPO₄ concentrations in all digesters. By the end of the 150-day study, the SPO₄ levels in all digesters returned to about 140 mg/L. It can therefore be reasonably concluded that the addition of FW waste to the anaerobic digestion process has little impact on side-stream nutrient loadings.

Figure 22

Summary

Based on the experience gained from the batch co-digestion study of FW and SS sludge, a semi-continuous co-digestion study was conducted. Various combinations of FW and SS, 0%, 10%, 20% and 50%, along with seed sludge from DITP were added into six 4-liter digesters. One digester was initially fed with 100% FW but failed about 50 days into the study, and so was converted to a second control reactor (0% FW). The SRT of the reactors was maintained at 28 days for the first 73 days of the study and then switched to 22 days for the rest of the 150-day study period to better match the SRT at DITP. Compared to the control reactor, percent increase in VS in the digester reactors at the start of the study ranged from 0% to 65.9% as the ratio of FW in the feed sludge increased from 0% to 50%.

The results of the co-digestion study showed that VSR based on VS loadings increased from approximately 65% to 77% as the ratio of FW in the feed sludge increased from 0 to 50%. Also, cumulative biogas production in the reactors during the 150 days of the semi-continuous digestion period increased as the ratio of FW to feed sludge increased. The amount of biogas production varied from approximately 12 to 15 cf/lb VS destroyed. The highest biogas yield was obtained in the reactors with a FW/feed sludge ratio of 10 - 20%.

The impact of FW addition on the digester side-stream was evaluated by monitoring COD, STN and SPO₄. The CODs for the FW digesters generally increased with increasing percentages of FW. The digester reactor with a FW feed of 50% generated the highest COD values, starting out the study at around 25,000 mg/L and finishing at about 30,000 mg/L. The COD in the control digesters typically averaged around 21,000 mg/L throughout the study. The concentration of STN in all digesters followed a similar pattern, starting out with values around 2,000 mg/L and then gradually increasing to around 2,500 mg/L around day 40. Following day 60, STN values in all digesters gradually decreased to values between 1,500 to 1,900 mg/L by the end of the 150-day study. SPO₄ in all digesters showed a similar trend. Each digester started out with an SPO₄ value of about 100 mg/L that increased to around 300 mg/L after 60 days. By the end of the 150-day study, SPO₄ levels in all digesters returned to about 140 mg/L. The decrease in STN and SPO₄ values also correlates with the SRT change from 28 to 22 days. It can therefore be concluded that the addition of FW to the anaerobic digestion process has little impact on side-stream nitrogen and phosphorus concentrations. However, the addition of FW increases the COD loadings of the side-stream, and digester recycle streams will see an increase in STN and SPO₄ loadings. An increase in STN recycle stream loading is noteworthy because DITP's effluent has a total nitrogen limit of 12,500 metric tons/year.

6.0 Application of Results to DITP

The results of the semi-continuous digestion study for 0%, 10%, 20% and 50% FW ratios were applied to actual operating data from DITP to obtain the following biosolids reduction and biogas production rates, as shown in Tables 15 and 16, respectively.

Table 15
Biosolids Production at DITP

	Current	10% FW	20% FW	50% FW
Solids In (DT/day)	245.5	245.5	245.5	245.5
FW Addition (DT/day)	0	24.5	49.1	122.8
Total Solids In (DT/day)	245.5	270.0	294.6	368.3
Solids Out (DT/day)	120.2	125.7	131.2	147.8
Reduction (%)	51.0	53.4	55.5	59.9

SRT (days)**	21.1	20.4	19.7	17.8

*Excess solids due to FW addition

**SRT was calculated based on 8 digester tanks in operation, 5.18% TS for SS and 14% TS for FW.

Table 16
Biogas Production at DITP

	KCSF	Increase (%)	Ft ³ Biogas/lb VS Reduced
Current	4,493	NA	17.93
10% FW	5,459	21.5	19.76
20% FW	6,254	39.2	20.10
50% FW	8,873	97.5	20.20

MWRA is planning to conduct a full-scale pilot plant investigation to further evaluate the co-digestion of FW and SS at DITP. In this investigation MWRA will evaluate the following FW feed applications to the operating anaerobic digesters at DITP:

- 7 DT/day FW applied to one digester
- 14 DT/day FW applied to one digester
- 21 DT/day FW applied to two digesters (10.5 DT/day to each digester)

Table 17 shows the amount of biosolids addition based on the abovementioned FW feed rates, the resultant SRTs, percent biosolids reduction and excess solids production. Table 18 shows the amount of biogas produced for the abovementioned FW feed rates, including percent increase and cubic feet of biogas produced per pound of VSR.

Table 17
Biosolids Production at DITP (per Digester) – Full-Scale Pilot Plant Investigation

	Current	7 DT/day	14 DT/day	21 DT/day*
Solids In (DT/day)	30.69	30.69	30.69	30.69
FW Addition (DT/day)	0	7	14	10.5
Total Solids In (DT/day)	30.69	37.39	44.69	41.19
Solids Out (DT/day)	15.04	16.45	18.23	17.46
Reduction (%)	51.0	56.0	59.2	57.6
Excess Solids Produced ** (DT/day)	0	1.41	3.19	2.42
SRT (days)	21.1	19.5	18.0	18.7

*Results are listed per digester, based on 10.5 DT/day FW addition to each of 2 digesters

** Excess solids due to FW addition

Table 18
Biogas Production at DITP (per Digester) – Full-Scale Pilot Plant Investigation

	KCSF	Increase (%)	Ft ³ Biogas/lb VS Reduced
Current	561.6	NA	17.93
7 DT/day	807.6	43.8	20.06
14 DT/day	1,053.0	87.6	20.15
21 DT/day*	938.5	67.1	20.34

*Results are listed per digester, based on 10.5 DT/day FW addition to each of 2 digesters

Assumptions:

1. TS concentration of FW was assumed to be 14%.
2. VS concentration of 100% FW was assumed to be 93% TS.
3. VSR for 100% FW was assumed to 83.4%
4. Biogas production was calculated based on the average biogas yield obtained for the corresponding FW/SS ratio during the 22-day SRT period of the semi-continuous study.

Based on the above data, it may be concluded that:

1. At 7 DT/day, 14 DT/day and 10.5 DT/day FW addition per digester, the excess solids produced is estimated at 1.41 DT/day, 3.19 DT/day and 2.42 DT/day, respectively, per digester.
2. At 7 DT/day, 14 DT/day and 10.5 DT/day FW addition per digester, the unit biogas production is estimated at 20.06, 20.15 and 20.34 ft³/lb VSR, respectively.

7.0 Conclusions and Recommendations

Based on the results of the semi-continuous bench-scale study of anaerobic co-digestion of various ratios of an engineered blend of FW and SS from DITP, the following conclusions can be drawn:

1. The addition of FW to SS at varying ratios of 0 to 50% showed no adverse effect on the co-digestibility of FW and SS.
2. As the ratio of FW to SS increases, VS content of the mixed FW and SS also increases.
3. As the ratio of FW to SS increases, the percentage of VSR also increases. Based on the VSR percentages compared to VS loading for the 22-day SRT for the control, 10% FW, 20% FW and 50% FW reactors, we calculated an average net VSR of 84% for FW.

4. An increase in the FW to SS ratio results in an increase in biogas production.
5. The addition of FW to SS of up to a 50% ratio is not expected to increase the concentration of STN and SPO₄ in the side-streams. However, an increase of STN and SPO₄ loading is expected in the recycle stream.
6. As the ratio of FW to SS increases, the concentration of soluble COD in the digester increases. This increase in soluble COD would benefit from an increase in SRT
7. The change in SRT from 28 days to 22 days had a significant impact on several parameters of the study including pH, COD, STN and SPO₄. The shorter SRT resulted in a more stable pH, a slight elevation in COD concentration, and a decrease in STN and SPO₄ concentrations in the side-streams.
8. The addition of FW to the DITP anaerobic digesters up to an amount equal to 50% of the feed sludge will increase biosolids reduction and enhance biogas production without having an adverse impact on digester stability.
9. Study results indicate that DITP could play a significant role in helping to meet the FW disposal diversion goals of the Massachusetts Solid Waste Master Plan while reducing the facility's dependence on fossil fuel, increasing its production of biogas, and becoming more energy-efficient.
10. We recommend MWRA conduct a follow-up large-scale pilot plant study at DITP to verify the results of the bench-scale laboratory study presented in this report, optimize FW percentages in the digester feed sludge and evaluate their impact on biosolids reduction, biogas production, digester heating requirements, sludge production, and sidestream loadings.
